10th International Conference on Hydrogen Safety (ICHS 2023) Québec City, Québec, Canada September 19-21, 2023

This paper describes objective technical results and analysis. Any subjective views or opinions that might be expressed in the paper do not necessarily represent the views of the U.S. Department of Energy or the United States Government.

SAND2023-09260C

MOTIVATION

Alternative vehicles use of infrastructure requires a **reassessment of safety**

Fire response curves based on hydrocarbon fueled vehicles and cargo are used in the structural design of tunnels

Similar to hydrocarbon vehicles, hydrogen vehicles pose **thermal hazards**, but with characteristics that differ:

- Hotter flames
- o Shorter duration
- Highly directed
- o Buoyant flammable cloud

High-fidelity **modeling simulations** have been used to support single tunnel safety studies

- High computational costs
- Single tunnel geometry / accident scenarios considered

Goal

Develop a **generalized framework** for assessing safety of hydrogen vehicles in tunnels

- Variety of tunnel geometries
- Different vehicle types/classes
- Multiple crash scenarios

Will require approach to be relatively **computationally inexpensive**

• Allowing assessment of multiple scenarios

Adaptable to alternative fueling types for comparisons

Enable safety of $\rm H_2$ vehicles in tunnels to be consistently and specifically assessed nationwide

OUTLINE

Modeling Approach **Tunnel Geometry Characterization** Tank Blow Down Calculations Parametric Sensitivity Studies o Tank Size o Tank Volume • Tank Orifice o Tank Fullness • Fuel Type **Fuel Dispersion Consequence** Metrics Conclusions

ACCIDENT SCENARIO

Flipped over light duty vehicle

Exposed to external fire causing 2.25 mm Thermal Pressure Relief Device (**TPRD**) to activate

 GH_2 fuel tank is 125 L at 70 MPa

○ ~5 kg of fuel

GH₂ released through TPRD as jet directed toward the tunnel ceiling

- Ceiling is 3.93 m above release point
- Fuel may immediately ignite as a jet fire or have delayed ignition causing an unconfined overpressure event

Illustration of accident scenario; image taken from first responder training from www.h2tools.org

Also consider **CNG** and **LPG** vehicles for comparisons

- $_{\odot}$ Assumed same TPRD size as GH_{2}
- \circ 60 L tank at 25 MPa for CNG (*modeled as CH*₄)
- $_{\odot}$ 50 L tank 80% full of liquid for LPG

MODELING APPROACH

Physics Models

HyRAM+ V5.0 Python backend provides temporal blowdown calculations of releases from vehicle fuel tank

- Release assumed to be gaseous
- Choked flow throughout most of blowdown
- Density evolved for LPG instead of pressure

Steady state jet plume and jet flame models of gaseous releases based on pressures and mass flow rates for each blowdown time point

Consequence Models

Visible flame length and **positional radiative heat flux** predictions based on steady state jet flame calculations

Flammable mass and **maximum unconfined overpressure** from jet plume calculations

• Overpressure values from 1 m away horizontally to better capture scaling behavior

TUNNEL GEOMETRY CHARACTERIZATION

Extracted tunnel characteristic data from U.S. Federal Highway Administration's National Tunnel Inventory¹

Annual data on tunnel characteristics and inspection results

- **Characteristics**: location, year built, average traffic load, length, ...
- Inspected **elements**: tunnel liner, roof girders, ceiling slab, ceiling panels, ...

Use tunnel characteristic/element statistics to focus safety analyses

Determine prevalence and relevance based on **prioritization** such as high daily traffic loads

Tunnel Shape

Radiative heat flux to ceiling quickly diminishes after impingement ceases

PARAMETRIC SENSITIVITY STUDY

• Holding other parameters at nominal values

Reducing tank pressure decreases extent and duration of consequences

Increasing tank size increases duration of consequences

Increasing orifice size increases consequence magnitude but decreases duration

Varying input parameters allows alternative accident scenarios to be compared

TANK VOLUME STUDY

Varying tank volume provides insights into how different **vehicle classes** will impact the blowdown behavior

125 L to 2,500 L meant to span from light duty to heavy duty

Larger tanks increase the duration of consequences but not the magnitude for same leak/orifice size

 Heavy duty vehicles may operate at lower pressures reducing consequence magnitude

Increasing volumes 2x (250 L), 5x (625 L), and 20x (2500 L) from nominal increases total blowdown durations equivalently

Time the jet flame impinges on the ceiling increases

TANK ORIFICE SIZE STUDY

Varying orifice diameter through which fuel is released (**TPRD**) between 0.5 mm and 10 mm
Reflects impact of different TPRD designs or potential leaks from the vehicle

Increasing the orifice size increases the consequence magnitude but decreases the duration

Orifice Diameter (mm)	Maximum flame length (m)	Maximum flammable mass (kg)	Total blowdown time (min)
10	30.7	2.76	0.25
0.5	1.54	3.72E-04	98.2

TANK FULLNESS STUDY

Varying fullness of tank (% full) between 100% and 12.5%
Assuming full vehicle tank at time of accident is conservative; exploring impact of different realities

Less full tanks have lower consequences for shorter durations

Flame from ¼ full tank never reaches the ceiling and does not reach peak overpressures necessary to cause extreme damage

FUEL TYPE STUDY

Comparisons against other fuels provides perspective for H₂ predictions

o Comparable, fieldable CH₄ and LPG vehicle tanks estimated; not equal masses

 CH_4 and H_2 consequences more similar in duration and characteristic

LPG consequences less severe but longer duration due to larger mass of fuel

FUEL DISPERSION

Possibility of **accumulating large flammable mass** in tunnels is another safety concern

Initial investigation looks at **physically impossible bounding case** of total volume of fuel at lower flammability limit (4% by volume) for different tank sizes • LFL volume compared to tunnel volume statistics

Tunnel volumes estimated based on tunnel shape, vertical clearance, width (roadway, sidewalks), and length from **National Tunnel Inventory** data

• Top 20% in terms of daily traffic

Light duty vehicles (5/10 kgs H₂) only fill up volumes (1,500/ 3,000 m³) smaller than smallest tunnel considered (5,200 m³)

Ignoring dissipation and ventilation

CONCLUSIONS

First steps in developing a **generalized tunnel safety analysis framework** for alternative fueled vehicles

Representative ranges of tunnel characteristics can be found in **U.S. DOT's National Tunnel Inventory** (*over 550 tunnels*)

Lower-order consequence models enable efficient exploration of a wide range of crash scenario parameters (tank volume, orifice size, ...) and comparisons to other fuel types

Consequence models provide **temporally evolving** estimates of **hazards** potentially impacting tunnel structures including flame impingement and peak overpressures

Future work:

Integrate information from tunnel design codes and standards

• Material response characterization to determine potential damage extents

CONSEQUENCE MODELS STEADY STATE ASSUMPTION

HyRAM+ v5.0 consequence models used steady state models whose mass flow rates do not exactly match those from blowdown calculations when matching pressure values

Error is relatively small, but steady state flowrates are smaller than those predicted by blowdown resulting in underprediction of consequences

Largest errors occur early in blowdown when consequences are still typically damaging even in steady state predictions

Comparison of mass flow rates predicted by HyRAM+ blowdown calculations and steady state consequence models
